

# 1 The home: derived, never registered

**One path per page:** existence of the file is the whole state.

```
<page>/slide/<page>-deck.html
derived from the page's own path, the way Draw derives its owner
no manifest row, no registry: HEAD the path and you know
```

A folded page (<name>/<name>.md) owns the `slide/` folder, and the deck's filename is the page stem plus `-deck.html`. Both doors below derive this path from the page they are on, so nothing keeps a list that could drift. When the file is absent the surfaces say so and offer the button, and nothing generates a deck behind your back.

## 2 The two doors

**Where a deck opens:** the shell tab and the page panel, one loader behind both.

|             |            |                                |
|-------------|------------|--------------------------------|
| the shell's | Slides tab | beside Chat and Draw, with the |
|             |            | bar riding above the frame     |
| the page's  | panel      | a resizable right split, with  |
|             |            | regenerate in its header       |
| ?plain      |            | or the deck comes back wearing |
|             |            | the operating shell            |

Both doors HEAD the derived path and show the saved deck, or a pointer to the button when none exists. Every load is cache-busted, so a freshly written deck appears on the next click and a stale iframe can never survive its file.

## 3 Regenerate: one click, one authored deck

**The loop:** what the button does and what it overwrites.

```
click --> POST /_board/autodeck {file, prompt?}
--> live/autodeck.py runs `claude -p` on the page's .md
--> slide/<page>-deck.html replaced --> frame reloads
a few minutes . the status word says so while it thinks
```

The ask box is optional: empty means present the page's argument, and a typed ask steers the talk's emphasis. The `<head>` with its asset hops is computed server-side from real paths, so the model's freedom starts at `<body>` and a generated deck can never 404 its own stylesheets. The server validates before writing: a complete document, at least three slides, the asset links present, or the deck is refused and the old file stands. Regeneration always overwrites, so a lasting correction belongs on the PAGE, which is what every regeneration reads.

## 4 What a deck is

**The form:** html-ppt's shell, this board's voice.

```
academic-report theme . T cycles the short gallery  
  move . F fullscreen . O overview . S presenter mode  
every slide carries speaker notes, surfaced by S  
scripts blocked? a data-js stamp is absent and CSS flattens  
  the deck to one fragment-picked slide, so it still reads
```

A deck is six to nine slides: a cover, a closer, and distilled middles built from the page's own emoji, numbers, and quoted rulings. The deck links at the html-ppt skill's assets by relative path, so a theme improvement reaches every deck with no rebuild. Nothing from the skill is copied into the board, and the board contributes no CSS of its own.
